WELCOME
A Letter from BODY WORLDS

Dear Students,

Have you ever watched a professional basketball player seem to float in air as he or she leaps up to dunk the ball in the basket? Or maybe you watched athletes competing at the Olympics, and wondered, “How did they do that?”

Well, our bodies are pretty amazing. The more we learn about ourselves and how our bodies work, the better we can take care of ourselves and others, and, the healthier we will be – making us better on the football pitch, basketball or tennis court, riding a bike or just walking down the street.

“Gunther von Hagens’ BODY WORLDS: The Original Exhibition of Real Human Bodies” was developed by a German doctor and anatomist to help people understand how their bodies work by letting them look inside real human bodies. When you visit with your school or family, you will see exactly how your organs look and what happens to them when certain diseases take over. You will see how smoking destroys lungs and how bones, muscles and ligaments all work together so you can play sports, dance, or skate.

The activities inside this guide will help you learn more about the human body. Come visit us to see BODY WORLDS.

You’ll really get to know yourself!

Cool Fact
Dr. Gunther von Hagens invented Plastination in 1977.

Conceptual Designer of BODY WORLDS and President and CEO of the Institute for Plastination.
Exhibition Overview

Gunther von Hagens’ BODY WORLDS uses the science of Plastination allowing visitors to see how human bodies are put together.

The exhibition also teaches how different anatomical systems work in the human body.

This student supplement explores several of the systems featured in the exhibition, including the locomotive system, the nervous system, the respiratory system, the cardiovascular system and the digestive system.
What is BODY WORLDS?
BODY WORLDS is the first exhibition of its kind to inform the visitor about anatomy, physiology, and health by viewing REAL HUMAN BODIES. The specimens on display were preserved through Plastination, the preservation process invented by Dr. Gunther von Hagens in 1977, while he was working as an anatomist at the University of Heidelberg. Since the beginning of the exhibition series in Japan in 1995, more than 45 million visitors in over 120 cities in Americas, Europe, Asia and Africa have seen the world’s most successful traveling exhibition.

BODY WORLDS Vital presents a special collection of specimens designed to show visitors the basics for human health and wellness. “Vital” tells the fascinating story of how best to fight life-threatening diseases – such as cancer, diabetes and heart ailments – through healthy choices and lifestyle changes. The exhibition inspires visitors to assert themselves and to claim responsibility for their own health and well-being.

What does BODY WORLDS show?
Each BODY WORLDS exhibition contains real human specimens, including whole-body plastinates as well as individual organs, organ configurations, and transparent body slices. The spectacular plastinates in the exhibition take the visitor on an exciting journey of discovery under the skin. It provides a wide-ranging insight into the anatomy and physiology of the human body. In addition to organ functions, common diseases are described in an easily understood manner by comparing healthy and affected organs. They show the longterm impact of diseases and addictions, such as tobacco or alcohol consumption, and demonstrate for example the mechanics of artificial knee and hip joints.

How is BODY WORLDS Vital unique?
While all of the BODY WORLDS exhibitions focus on general anatomy revealed through Plastination, each exhibition is currently being shown with dedicated themes – on the body’s capability and vitality (BODY WORLDS Vital), cardiology and the heart (BODY WORLDS & The Story of the Heart), human development, longevity and ageing (BODY WORLDS & The Cycle of Life), the story of the human body in the 21st century (BODY WORLDS: Pulse), the influence that ‘happiness’ has on our health (BODY WORLDS: The Happiness Project) and on prescriptions for healthy living (BODY WORLDS RX).

The exhibitions show a multitude of brand new plastinates and offer every visitor, even the ardent BODY WORLDS visitor, a fascinating exhibition experience.

All BODY WORLDS exhibitions generally present different whole-body plastinates which each vary in pose and display.

Are there animals in the BODY WORLDS exhibitions, as well?
A few BODY WORLDS exhibitions have a few animal specimens on display. Due to the great popularity of the animal plastinates, Dr. Gunther von Hagens and Dr. Angelina Whalley were encouraged to create the new exhibition BODY WORLDS of Animals which also tours the world under the name ANIMAL INSIDE OUT. The display features the most popular species in the animal kingdom. Better than any textbook, this fascinating exhibition shows the complex, amazing biology of the natural world’s most remarkable creatures and their nervous system, bones, muscles, and organs. Look out for future tours.

What is the goal of the exhibition?
BODY WORLDS aims to educate the public about the inner workings of the human body and shows the effects of poor health, good health and lifestyle choices. It is also presented to motivate visitors to learn more about the science of anatomy and physiology.

Why is it important for the public to see these exhibitions?
The organisers of BODY WORLDS believe that when people understand more about how the body works, they are more likely to choose healthy lifestyles. They also hope it will inspire visitors to learn more about the life sciences. Knowledge about what the human body looks like and how it functions is basic life science information that should be available to everyone.

Would I be able to learn just as much from books or models of the human anatomy?
The use of authentic specimens allows a thorough examination and study of disease, physiology and anatomy that you cannot find in models, textbooks or photos. In addition, the exhibition allows visitors to understand that each and every body has its own unique features, even on the inside. The experience in other cities has clearly demonstrated that real specimens fascinate visitors in a way that models cannot.
What is Plastination?
Plastination is a unique process invented by Dr. Gunther von Hagens to preserve specimens for medical education. The process replaces bodily fluids and fat in specimens with fluid plastics that harden after vacuum-forced impregnation (see in this guide for an explanation of this method). After the bodies are shaped into lifelike poses, they are hardened with gas, heat or light. The plastinates show how our bodies move in everyday life, as well as during athletic activities. For more information about Plastination, go to www.bodyworlds.com.

Where did the specimens on display come from? Will we know who the plastinates are or how they died?
The BODY WORLDS exhibitions rely on the generosity of body donors; individuals who requested that, upon their death, their bodies could be used for educational purposes in the exhibition. All the whole-body plastinates and specimens are from these body donors. Donor identities and causes of death are not disclosed.

Currently there are more than 17,000 donors registered in the body donation program of the Institute for Plastination. For more information please visit the body donation section of www.bodyworlds.com. BODY WORLDS exhibitions are based on an established body donation program through which the body donors specifically request that their bodies could be used in a public exhibition after their deaths.

Why are the plastinates posed the way they are?
The poses of the plastinates have been carefully thought out and serve educational aims. Each plastinate is posed to show different anatomical features. For instance, the athletic poses illustrate the use of muscle systems while playing sports. The poses are chosen to highlight specific anatomical features and allow the visitor to compare the plastinate to his or her own body.

Will I be able to touch any of the plastinates?
While you will be able to get very close to the plastinates, as a rule, visitors are not allowed to touch the exhibits.

Is this exhibition appropriate for children?
45 million people, including millions of young children, have viewed the BODY WORLDS exhibitions around the world. If you are considering bringing children or school groups to BODY WORLDS, visit our online resources section to find out how to use the exhibition as a learning experience.

Who should see BODY WORLDS?
Anyone interested in learning what makes us human. Students of all ages will find the exhibits fascinating.

Is there an audio tour?
Some exhibitions offer audio guides for an additional fee. The audio tours are designed for the general public. They are available in English and other languages. There are no personally guided tours through the exhibition.

Have the ethical questions about this exhibition been discussed?
Before the North American premiere of BODY WORLDS, a wide committee of theologians, ethicists, academics and medical experts thoroughly discussed ethical questions about the exhibition. Guided by the California Science Center, Los Angeles, they wrote an Ethics Review of the origins of bodies in BODY WORLDS. It can be downloaded at www.bodyworlds.com

What educational materials are provided?
Teachers are invited to pre-register their schools interest by visiting xpo.co.nz/events/body-worlds-schools

Once the exhibition opens, teachers and educators will be invited to one of the FREE Educator preview tours of the exhibition. In addition to attending the preview tour, teachers will also have access to Worksheets and Family Guides to facilitate an authentic learning experience like no other.

How long can you stay inside the exhibit?
You can stay as long as you like, within the opening hours. We recommend allowing yourself 60-90 minutes.

The length of time will vary on how long each visitor wishes to examine each specimen and read the information. An audio tour will add to your time in the exhibition. Re-entry to the exhibition is not allowed once you exit.
What is Plastination?

The Plastination Process

Preservation by Plastination

1. Embalming and Anatomical Dissection

The first step of the process involves halting decay by pumping formalin into the body through the arteries. Formalin kills all bacteria and chemically stops the decay of tissue. Using dissection tools, the skin, fatty and connective tissues are removed in order to prepare the individual anatomical structures.

2. Removal of Body Fat and Water

In the first step, the body water and soluble fats are dissolved from the body by placing it into a solvent bath (e.g., an acetone bath).

3. Forced Impregnation

This second exchange process is the central step in Plastination.

During forced impregnation a reactive polymer, e.g., silicone rubber, replaces the acetone. To achieve this, the specimen is immersed in a polymer solution and placed in a vacuum chamber. The vacuum removes the acetone from the specimen and helps the polymer to penetrate every last cell.
4. Positioning

After vacuum impregnation, the body is positioned as desired. Every single anatomical structure is properly aligned and fixed with the help of wires, needles, clamps and foam blocks.

5. Curing (Hardening)

In the final step, the specimen is hardened. Depending on the polymer used, this is done with gas, light or heat.

Dissection and Plastination of an entire body requires about 1500 working hours and normally takes about one year to complete.

Slice Plastination

Slice Plastination is a special form of Plastination. First, the body is frozen and cut into 2 to 8 millimetres thick slices. Instead of silicone, the body is treated with polyester or epoxy resin during this process.
Interview with Dr. Gunther von Hagens

Children interview Dr. Gunther von Hagens, creator of BODY WORLDS & inventor of Plastination
Were you ever scared to work with dead bodies?

Dr. von Hagens: When I was about six years old, I was very sick and nearly died. I was in hospital for many months and became very comfortable in that environment of the sick and dying. The doctors and nurses who cared for me became my heroes and I wanted to be like them.

Later, when I worked in a hospital as an orderly and then a nurse, (long before I became a doctor), one of my duties was to transport the dead to the morgue. Other workers didn’t like this job because it frightened them, but I was never afraid. Being afraid of death is not a good way to live.

Were the people in the exhibit old when they died?

Dr. von Hagens: The people who donated their bodies for Plastination and to educate all of us about health are of various ages. Some were old, but others were young in the prime of their life. Each person is different, not just on the outside but also on the inside. Even after more than 40 years as an anatomist, I have never seen two hearts that look the same.

Where did the idea for BODY WORLDS come from?

Dr. von Hagens: When I used to teach anatomy to students in medical school in the 1970s, I had to use illustrated anatomy atlases and picture books to show the organs and body systems. I tried to use real human organs and specimens, but at that time the specimens were preserved in blocks of plastic so you could not touch them or study the placement of the organs properly.

I realised one day that if the plastic was inside the body and not outside it, the specimen would be rigid and easy to grasp study and work with. I was only trying to solve a problem; I wanted to educate my students so they would become better doctors, as I don’t think doctors should be poking around inside your body and operating on you if they don’t know important things about it.

But something very unusual began to happen after I began to plastinate organs and specimens. The janitors and secretaries and office workers at the university began to stop by the lab; they were fascinated by the plastinates. This was when I began to think of anatomy for lay people, which is what BODY WORLDS is. It is very different from anatomy for medical professionals because it has to be interesting and dynamic and not scary to look at.

How long does it take to prepare the bodies for display?

Dr. von Hagens: Plastination takes a very long time. A whole body can take up to 1,500 hours to prepare. The specimen which has to date taken the longest to produce is a plastinated elephant that weighs 3.2 tons and took three years to complete.

What happens to the skin once it is removed from the bodies?

Dr. von Hagens: Each body is an anatomical treasure. Human remains must be handled carefully and respectfully. All human remains that are not plastinated are cremated and buried.

How do you get people to donate their bodies?

Dr. von Hagens: I have never recruited body donors. People offer their bodies for Plastination for several reasons: they want to leave a legacy for future generations; they don’t like the effects of decay and decomposition that take place after death; or they don’t like traditional burials.
Making Motion Happen

The locomotive system makes movement possible. It consists of the bones that make up the skeleton, the joints that hold the bones together, and the muscles that contract and relax to actually make you move.

The skeleton is the framework of the body, and is made up of bones and cartilage. Bone is made mostly of calcium, which is why it is important to eat calcium-rich food to keep your bones strong. Inside the bone is sponge-like matter called bone marrow. This makes bones light so people can move easily, but strong enough to support body weight. Bone marrow also produces red and white blood cells. Red blood cells have haemoglobin and carry oxygen. White blood cells produce antibodies to attack bacteria, infections and diseases.

The skeleton has many jobs. It provides protection to internal organs, it supports the body and gives it its shape, and it provides a place for muscles to attach.

Bones are important to almost every movement we make. Bones couldn’t move a pencil, though, without help from muscles. Muscles consist of cells that contract. Muscles and bones are connected by tendons, which are similar to ropes. When a muscle contracts, it pulls the tendon, which then tugs on the bone, and everything moves.

Although it may seem easy to do something like throw a ball, it’s actually complicated when looked at inside the body. To make the motion of throwing, many muscle groups in the shoulders, arms, chest, abdomen, and even legs must be used! Each of these groups must work together with nerves in order for motion to occur. And all this happens in a fraction of a second!
Voluntary muscles are used when you throw a ball. These are the muscles we can control. People also have involuntary muscles, which we cannot control, such as the heart and the stomach. Another important part of the locomotive system are the joints. Joints are positioned between major bones that come together and help you to move and bend.

There are different kinds of joints, including ball and socket joints in the hips and hinge joints at the knees and elbows.

Learn with BODY WORLDS

The bones of the human skeleton give the body both strength and structure. A strong and healthy skeleton is important for every person for both work and recreation.

Think of three things that you do every day that involve the use of certain bones.

Joints are surrounded by capsules containing fluid that help the bones move smoothly.

Cool Fact
At birth, humans have 300 bones. As a baby grows, however, many of the smaller bones fuse together so that adults have just 206 bones.
The Messenger and the Boss

The nervous system is the system of the body that controls movements, thoughts and emotions throughout the body. Without it, you wouldn’t be able to function!

There are two parts to the nervous system: the central nervous system and the peripheral nervous system.

The central nervous system includes the brain and the spinal cord. They work together with nerves to send messages back and forth between the brain and the rest of the body. The brain controls the system. It has five parts: the cerebrum, the cerebellum, the brain stem, the pituitary gland and the hypothalamus.

The cerebrum is the biggest part of the brain and controls thoughts, language and voluntary muscles, which are the muscles you can control. You also use the cerebrum when you think hard and when you need to remember things. The cerebellum is a lot smaller than the cerebrum, but still very important. It controls balance, movement and coordination. If it weren’t for the cerebellum, you wouldn’t be able to stand without falling!

The brain stem connects the rest of the brain to the spinal cord.

It’s the part in charge of major things that keep you alive like breathing, blood pressure, and digesting food. Unlike the cerebrum, the brain stem controls the involuntary muscles — the ones that work without you thinking about it, such as the heart and stomach.
The tiny pituitary gland produces and releases hormones into the body—hormones like those that help you grow and change. Finally, the hypothalamus regulates your body temperature, your emotions and hunger and thirst.

The brain has many jobs, but it needs help from nerves and the spinal cord, too. Every action you do happens because your brain, your nerves and your spinal cord work together.

The nervous system includes millions and millions of neurons, which are microscopic cells. When you do something, messages travel from the neurons to your brain. The peripheral nervous system is composed of the nerves and neurons that go outside the central nervous system to operate the body’s limbs and organs. It is here that everything gets connected.

Next time you take a test, drink a glass of water, laugh, or do anything at all, thank your nervous system. Actually, you can thank it right now since it just helped you read this!

Learn with BODY WORLDS

The nervous system carries messages to the brain that make it possible for the body’s five senses to work.

The five senses are touch, taste, hearing, sight and smell. Explore the five senses by writing about one of your favorite things for each sense.

For example you may enjoy listening to music, because it helps you concentrate. This relates to your sense of hearing.

Cool Fact

The nervous system carries messages from the brain to other parts of the body at more than 400 kilometers per hour.
The organs of the respiratory system work together, along with other body systems, to ensure that the cells of the body receive the oxygen they need to live.

When you breathe in, the muscles of your chest expand. Your diaphragm lowers and creates lower air pressure in your lungs than in the world outside. This causes air to enter through the nose or mouth. Once air enters, it travels past your oesophagus, sometimes called the "foodpipe," and is moistened as it goes down the trachea, or "windpipe," into the lungs. As the air enters the lungs, the lungs expand outward.

Once inside the lungs, the air travels through tubes, called bronchi, into smaller tubes called bronchioles, which get smaller and smaller until they reach the alveoli which are sacs about the size of a grain of sand.

It is through the walls of the alveoli that the oxygen in the air you breathe enters the body’s blood, which flows past the alveoli. The blood receives the oxygen and, in return, passes carbon dioxide into the alveoli.

The cells of your body need oxygen to live, and carbon dioxide is the waste of things the cells do. Your red blood cells are little workers that carry the oxygen to the cells and take the carbon dioxide away.
Smoking, as we all know, makes the lungs less healthy and can lead to death.

One of the reasons for this is that smoking makes little structures called cilia stop working. Cilia move within the lungs to help clear things out that enter the lungs. Smoking disables or even kills them. Then harmful particles stay in the lungs.

Another bad effect of smoking is that chemicals from cigarettes will build up in the lungs, and the delicate alveoli can become thickened, swollen and unable to exchange oxygen and carbon dioxide with the blood in a healthy way. This condition leads to emphysema.

Think about it... Plants take the carbon dioxide that we release and use it, creating oxygen, which we need. We in turn take oxygen and turn it into carbon dioxide, which plants need. This is what is called a symbiotic relationship—one that is good for both organisms.

Try to think of other ways in which humans interact with nature in symbiotic relationships.

Learn with BODY WORLDS

A healthy respiratory system makes it possible for people to live active lives. Smoking causes problems for the respiratory system.

Make a list of five reasons why people shouldn’t smoke.
The heart is the central organ of the cardiovascular system and it doesn’t look much like the drawings found on Valentines. Cardio means heart, and the cardiovascular system is essential to our survival.

The cardiovascular system is sometimes referred to as the circulatory system because it’s responsible for the circulation of blood through the body. It consists of the heart, which is a muscular pumping device, and a closed system of vessels called arteries, veins and capillaries.

The cardiovascular system’s vital role is to provide a continuous and controlled movement of blood through the thousands of miles of microscopic capillaries that reach every tissue and cell in the body. Human survival depends on the circulation of blood to the organs, tissues and cells of your body.

Arteries carry blood enriched with oxygen away from the heart and veins carry blood that has used up its oxygen back to the heart. Through the heart and lungs, the blood gets a fresh supply of oxygen and delivers it to the rest of the body.

Twenty major arteries make a path through the tissues of the body. Then they branch out into smaller vessels called arterioles. These branch further into the capillaries, most of which are thinner than a hair—some so tiny, in fact, that only one blood cell can move through at a time.
Once the blood in capillaries delivers oxygen and nutrients, it picks up carbon dioxide and other waste. Then blood moves back through wider vessels, called venules. These eventually join to form veins, which deliver the blood back to your heart to pick up oxygen.

If all the vessels of this network were laid end to end, they would extend about 96,000 kms, far enough to circle the Earth more than twice!

Because all the tissues in the body rely on it, the cardiovascular system appears early in developing embryos—in the fourth week after fertilisation—and reaches a functioning state long before any other major organ system.

Learn with BODY WORLDS

The cardiovascular system is delicate and can be affected by many things. Fats and cholesterol, for example, can slow or even block the flow of blood in the body. Fats and cholesterol enter the body as food. One reason people are encouraged to limit the amount of fatty or oily foods they eat is to help prevent blockage.

Think of ten fatty foods and ten healthier options. For example, you may think of a doughnut as a fatty food and toast as an alternative.
Converting Food Into Energy

The body’s digestive system converts the food you eat into the energy you need to live.

The journey through your digestive system is a long one for food. It starts in the mouth, where teeth grind and tear the food into small pieces. Saliva then wets and softens the food and begins to dissolve carbohydrates. Once the food is properly mashed and wet, it is pushed by muscle action into the pharynx, or throat, and down the oesophagus, which leads to the stomach.

When food reaches the stomach it is mixed and broken down further by acids the stomach produces. The stomach protects itself from these acids by secreting a layer of mucus that lines the inside of the stomach. Some things, such as water and sugars, can be absorbed right out of the stomach and into the bloodstream. The things that need more digestion have further steps ahead of them.

When the stomach has made the food a liquid, the food passes through a valve into the small intestine. The small intestine has a large surface area because it contains villi. Villi are tiny little structures like very short hairs that stick out into the small intestine. Through the walls of the villi nutrients from food pass into the bloodstream. The bloodstream carries the nutrients to your cells so they can live.

Once all the useful nutrients have been taken from food in the small intestine, the unusable parts pass into the large intestine, or colon. In the large intestine, water is extracted from the waste and the material hardens into faeces. The faeces are passed out of the body when you go to the restroom.
Digestive helpers

The pancreas, liver, and gallbladder are all organs that do things important to the digestive system. The pancreas makes enzymes that help digest proteins, fats, and carbohydrates. The liver makes bile, which helps the body absorb fat.

Bile is stored in the gallbladder until it is needed. Enzymes and bile travel into the small intestine through ducts. Interestingly, people don’t really need the gallbladder. If it is removed, the bile just flows right into the small intestine and does its job.

Learn with BODY WORLDS

The digestive system breaks down the food that supplies the human body with energy. What foods would you eat if you needed energy for sports or active recreation?

Pick five foods you think would be good sources of energy. Then pair off and research your foods. Were they all healthy choices for getting the energy you needed?

Cool Fact

Your mouth makes about a litre of saliva each day, and you produce a total of about seven litres of digestive juices.
The Beauty of the Body

BODY WORLDS exhibitions teach us a lot about the science and anatomy of the human body. They also teach about the form and art of the human body.

Studies of anatomy have always been an important part of art education. Artists who know how the human body is put together and how its muscles work are better able to portray people in painting, sculpture, and other art forms. This knowledge is important, even if artists choose to represent the human form in abstract ways.

In the BODY WORLDS exhibits, Dr. Gunther von Hagens has positioned human figures to reveal how the body is put together and how it performs different tasks. He has also presented human figures in ways that highlight different body systems, such as muscles, internal organs or nerves and blood vessels.

The scientific choices he has made give us a new way to understand how human bodies work. At the same time, he has revealed how beautiful the form and systems of the human body are.

As visitors go through the exhibits, they learn the science and biology of anatomy. They also get to experience the artistic qualities of anatomy. This gives the exhibits appeal to all students, not just those in science classes.

Learn with BODY WORLDS

Understanding how the body works is important in many professions.

Think about what you want to be when you grow up. Write a short sentence or paragraph explaining why anatomy could be important in the job, and why.

Think like an artist

Artists sometimes like to focus on one aspect of a figure. In art, this may be done by emphasising one feature of a person, or showing the subject from an unusual angle or perspective.

Explore this idea by thinking about someone in your family. Reflect on what this person is like, or what you admire about him or her. Then think about what you would focus on if you were to portray this person in an artwork. Draw a sketch of your artwork and explain your ideas to the class.

Sports anatomy

Coaches need to know how to evaluate the physical skills and talents of players. These talents are often based on anatomy. Pick an athlete you admire. Then think about the different body systems explored in this guide. Write out which systems contribute most to the success of this athlete.
A WORD OF APPRECIATION

We would like to thank all those who have donated their bodies, without whom this exhibition would not have been possible.
